Introduction to CS 4104

Course Information

Instructor

- T. M. Murali, murali@cs.vt.edu
- ▶ Office Hours: 10am–11:30am, Mondays and Wednesdays

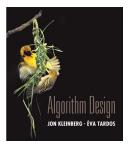

Course Information

- Instructor
 - T. M. Murali, murali@cs.vt.edu
 - Office Hours: 10am–11:30am, Mondays and Wednesdays
- Class meeting times
 - MW 2:30pm–3:45pm, Zoom

Keeping in Touch

- Course web site http://bioinformatics.cs.vt.edu/ ~murali/teaching/2021-spring-cs4104/, updated regularly through the semester
- Mailing list: class-cs-4104-13172-202101-g@vt.edu, announcements, including homeworks and exams.
- Canvas: grades, video recordings of classes, and homework/exam solutions

Required Course Textbook

- Algorithm Design
- Jon Kleinberg and Éva Tardos
- Addison-Wesley
- 2006
- ISBN: 0-321-29535-8

Course Goals

- Learn methods and principles to construct algorithms.
- Learn techniques to analyze algorithms mathematically for correctness and efficiency (e.g., running time and space used).
- Course roughly follows the topics suggested in textbook
 - Stable matching
 - Measures of algorithm complexity
 - Graphs (may skip)
 - Greedy algorithms
 - Divide and conquer (briefly)
 - Dynamic programming
 - Network flow problems
 - NP-completeness
 - Coping with intractability
 - Approximation algorithms
 - Randomized algorithms (if there is time)

Required Readings

- Reading assignment available on the website.
- Read **before** class.
- I strongly encourage you to keep up with the reading. Will make the class much easier.

Lecture Slides

- Will be available on class web site.
- Usually posted just before class.
- Class attendance is important.

Lecture Slides

- Will be available on class web site.
- Usually posted just before class.
- Class attendance is important. Lecture in class contains significant and substantial additions to material on the slides.
- I will not be taking attendance.

Homeworks

- Posted on the web site pprox one week before due date.
- Announced via Canvas.
- Prepare solutions digitally and upload on Canvas.
 - ► Solution preparation recommended in LATEX.
 - Do not submit handwritten solutions!

Homeworks

- Posted on the web site pprox one week before due date.
- Announced via Canvas.
- Prepare solutions digitally and upload on Canvas.
 - Solution preparation recommended in LATEX.
 - Do not submit handwritten solutions!
- Homework grading: lenient at beginning but gradually become stricter over the semester.
- Essential that you read posted homework solutions to learn how to describe algorithms and write proofs.

Examinations

- Take-home midterm.
- Take-home final (comprehensive).
- Prepare digital solutions (recommend LATEX).

Grades

- Homeworks: 7–8, 60% of the grade.
- Take-home midterm: 15% of the grade.
- Take-home final: 25% of the grade.

Honor Code

- Virginia Tech Graduate Honor Code applies to this class.
- In particular, assistance from the internet or anyone else is a violation of the Honor Code.
- Your work and solutions to the examinations must be only your own.
- Special policy for homeworks:
 - Work on the homework in pairs. You can bounce ideas off your partner.
 - Prepare solutions individually. Identical or similar solutions to any problem in a homework violate the Honor Code.

What is an Algorithm?

What is an Algorithm?

Dictionary A set of prescribed computational procedures for solving a problem; a step-by-step method for solving a problem. Knuth, TAOCP An algorithm is a finite, definite, effective procedure, with some input and some output.

What is an Algorithm?

Dictionary A set of prescribed computational procedures for solving a problem; a step-by-step method for solving a problem. Knuth, TAOCP An algorithm is a finite, definite, effective procedure, with some input and some output.

Two other important aspects:

- **Correct**: We will be able to rigorously prove that the algorithm does what it is supposed to do.
- Efficient: We will also prove that the algorithm runs in polynomial time. We will try to make it as fast as we can.

Stable Matching Problem

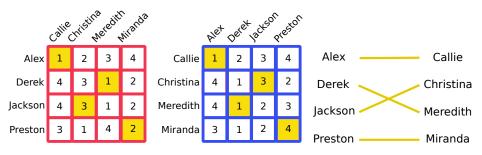

There are *n* men and *n* women.

Stable Matching Problem

Each man ranks all the women in order of preference. Each woman ranks all the men in order of preference. Each person uses all ranks from 1 to *n*, i.e., no ties, no incomplete lists.

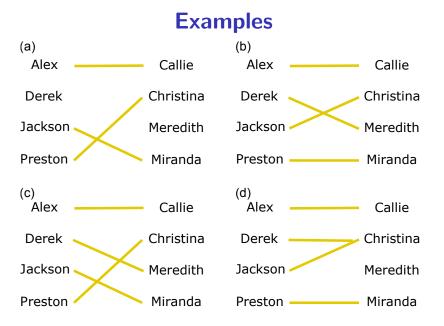

Stable Matching Problem

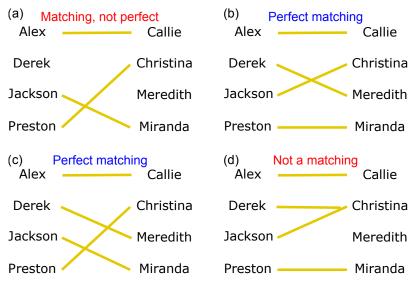

Matching: each man is paired with ≤ 1 one woman and vice versa.

Perfect matching: each man is paired with exactly one woman and vice versa.

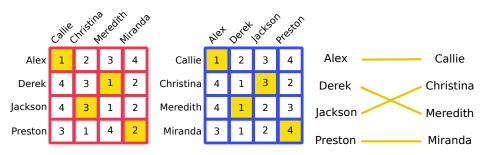

"Perfect": only means one-one mapping, not that people are happy with matches.

Examples

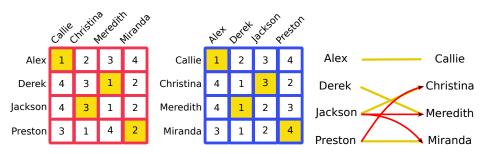

Stable Matching Problem

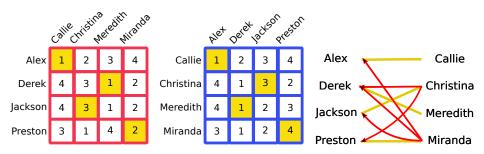

Are there problems with this matching?

Stable Matching Problem

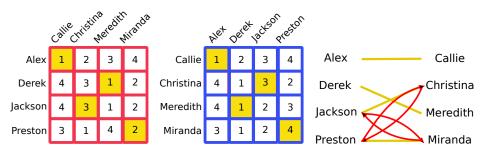

Are there problems with this matching?

Stable Matching Problem

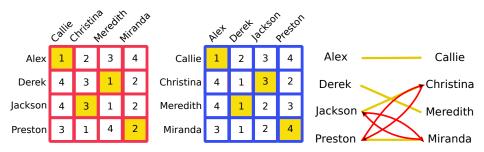

Are there problems with this matching?

Stable Matching Problem

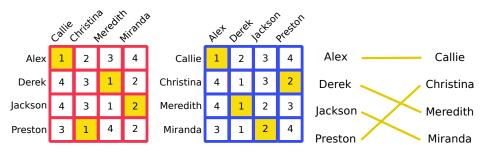

Rogue couple: a man and a woman who are not matched but prefer each other to their current partners.

Stable Matching Problem

Stable matching: A perfect matching without any rogue couples.

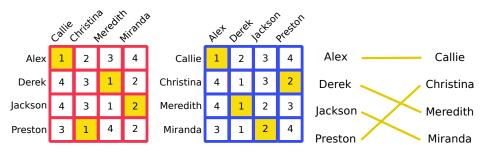

Stable Matching Problem

Stable matching: A perfect matching without any rogue couples.

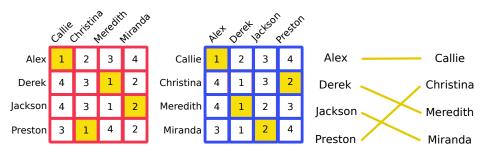

Stable Matching

Stable Matching Problem

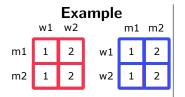

Stable matching: A perfect matching without any rogue couples.

Stable Matching Problem

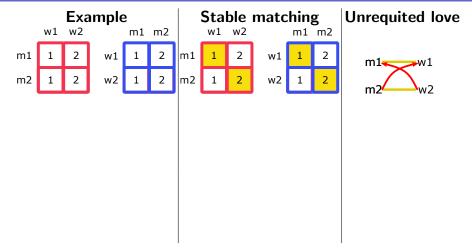

Questions

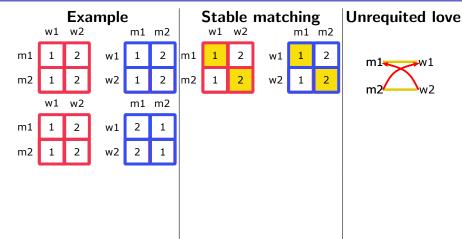

- Given preferences for every woman and every man, does a stable matching exist?
- If it does, can we compute it? How fast?

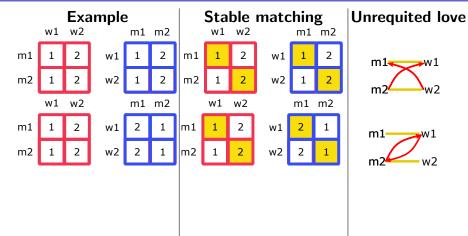

Stable matching

Unrequited love

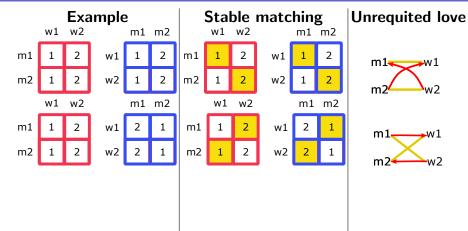

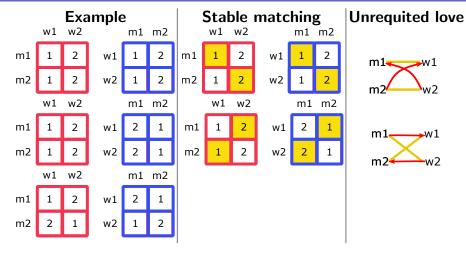

Data and Algorithm Analysis

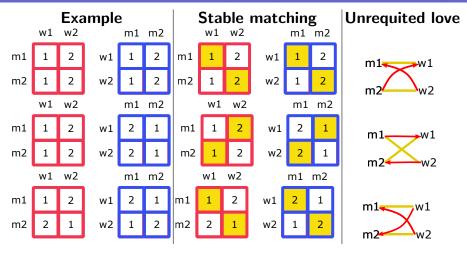

Stable Matching

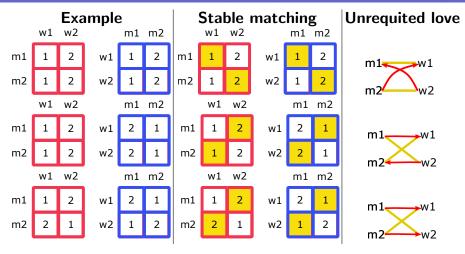

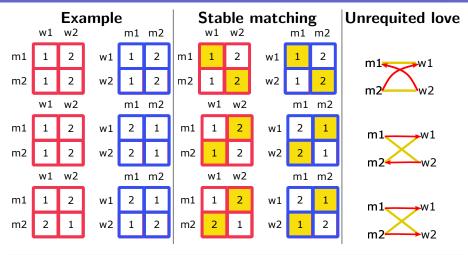

Data and Algorithm Analysis

Stable Matching

Challenge: Can you create an example that does not have a stable matching?

Gale-Shapley Algorithm

Each man proposes to each woman, in decreasing order of preference. Woman accepts if she is free or prefers new prospect to current fiance.

```
Initially, all men and all women are free
Set S of matched pairs is empty
While there is at least one free man who has not
   proposed to every woman
    Choose such a man m
    m proposes to the highest-ranked woman w on his list
    to whom he has not yet proposed
    If w is free, then
          she becomes engaged to m \operatorname{Add}(m, w) to S
    else if w is engaged to m' and she prefers m to m'
          she becomes engaged to m \operatorname{Add}(m, w) to S
          m' becomes free Delete (m', w) from S
    Otherwise, m remains free
Return set S of engaged pairs
```

Questions about the Algorithm

What can go wrong?

Questions about the Algorithm

What can go wrong?

- Does the algorithm even terminate?
- If it does, how long does the algorithm take to run?
- If it does, is S a perfect matching? A stable matching?

• Gale-Shapley algorithm computes a matching, i.e., each woman paired with at most one man and vice versa.

- Gale-Shapley algorithm computes a matching, i.e., each woman paired with at most one man and vice versa.
- Man's status:

- Gale-Shapley algorithm computes a matching, i.e., each woman paired with at most one man and vice versa.
- Man's status: Can alternate between being free and being engaged.
- Woman's status:

- Gale-Shapley algorithm computes a matching, i.e., each woman paired with at most one man and vice versa.
- Man's status: Can alternate between being free and being engaged.
- Woman's status: Remains engaged after first proposal.
- Ranking of a man's partner:

- Gale-Shapley algorithm computes a matching, i.e., each woman paired with at most one man and vice versa.
- Man's status: Can alternate between being free and being engaged.
- Woman's status: Remains engaged after first proposal.
- Ranking of a man's partner: Remains the same or goes down.
- Ranking of a woman's partner:

- Gale-Shapley algorithm computes a matching, i.e., each woman paired with at most one man and vice versa.
- Man's status: Can alternate between being free and being engaged.
- Woman's status: Remains engaged after first proposal.
- Ranking of a man's partner: Remains the same or goes down.
- Ranking of a woman's partner: Can never go down.

• Is there some quantity that we can use the measure the progress of the algorithm in each iteration?

- Is there some quantity that we can use the measure the progress of the algorithm in each iteration?
- Number of free men? Number of free women?

- Is there some quantity that we can use the measure the progress of the algorithm in each iteration?
- Number of free men? Number of free women? No, since both can remain unchanged in an iteration.

- Is there some quantity that we can use the measure the progress of the algorithm in each iteration?
- Number of free men? Number of free women? No, since both can remain unchanged in an iteration.
- Number of proposals made after k iterations?

- Is there some quantity that we can use the measure the progress of the algorithm in each iteration?
- Number of free men? Number of free women? No, since both can remain unchanged in an iteration.
- Number of proposals made after k iterations? Must increase by one in each iteration.
- How many total proposals can be made?

- Is there some quantity that we can use the measure the progress of the algorithm in each iteration?
- Number of free men? Number of free women? No, since both can remain unchanged in an iteration.
- Number of proposals made after *k* iterations? Must increase by one in each iteration.
- How many total proposals can be made? n^2 . Therefore, the algorithm must terminate in n^2 iterations!

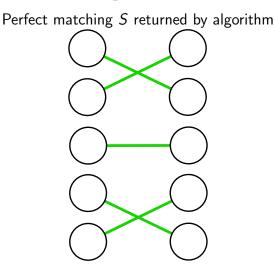

- Is there some quantity that we can use the measure the progress of the algorithm in each iteration?
- Number of free men? Number of free women? No, since both can remain unchanged in an iteration.
- Number of proposals made after *k* iterations? Must increase by one in each iteration.
- How many total proposals can be made? n^2 . Therefore, the algorithm must terminate in n^2 iterations!

Proof: Matching Computed is Perfect

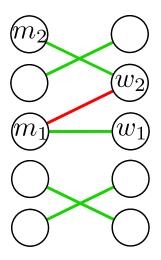

- Suppose the set *S* of pairs returned by the Gale-Shapley algorithm is not perfect.
- *S* is a matching. Therefore, there must be at least one free man *m*.
- *m* has proposed to all the women (since algorithm terminated).
- Therefore, each woman must be engaged (since she remains engaged after the first proposal to her).
- Therefore, all men must be engaged, contradicting the assumption that *m* is free.

Proof: Matching Computed is Perfect

- Suppose the set *S* of pairs returned by the Gale-Shapley algorithm is not perfect.
- *S* is a matching. Therefore, there must be at least one free man *m*.
- *m* has proposed to all the women (since algorithm terminated).
- Therefore, each woman must be engaged (since she remains engaged after the first proposal to her).
- Therefore, all men must be engaged, contradicting the assumption that *m* is free.
- Proof that matching is perfect relies on proof that the algorithm terminated.

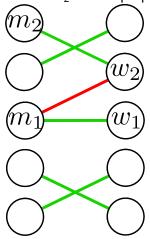

Not stable: m_1 paired with w_1 but prefers w_2 ; w_2 paired with m_2 but prefers m_1

January 20, 2021

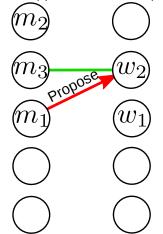

Not stable: m_1 paired with w_1 but prefers w_2 ; w_2 paired with m_2 but prefers m_1 $\Rightarrow m_1$ proposed to w_2 before proposing to w_1

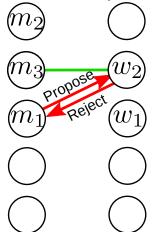

Rewind: What happened when m_1 proposed to w_2 ?

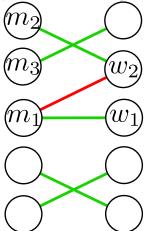

Case 1: w_2 rejected m_1 because she preferred current partner m_3 .

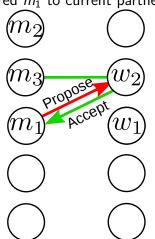

Proof: Matching Computed is Stable

Case 1: At termination, w_2 must prefer her final partner m_2 to m_3 . Contradicts consequence of instability: w_2 prefers m_1 to m_2

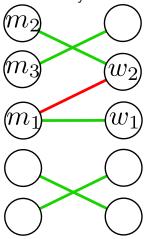

Proof: Matching Computed is Stable

Case 2: w_2 accepted m_1 because she had no partner or preferred m_1 to current partner m_3 .

Proof: Matching Computed is Stable

Case 2: By instability, we know w_2 prefers m_1 to m_2 . But at termination, w_2 is matched with m_2 , which contradicts property that a woman switches only to a better match.

Proof: Stable Matching (in Words)

- Suppose S is not stable, i.e., there are two pairs (m_1, w_1) and (m_2, w_2) in S such that m_1 prefers w_2 to w_1 and w_2 prefers m_1 to m_2 .
- m_1 must have proposed to w_2 before w_1 because
- At that stage w_2 must have rejected m_1 ; otherwise, the algorithm would pair m_1 and w_2 , which would prevent the pairing of m_2 and w_2 in a later iteration of the algorithm. (Why?)
- When w₂ rejected m₁, she must have been paired with some man, say m₃, whom she prefers to m₁.
- Since m_2 is paired with w_2 at termination, w_2 must prefer to m_2 to m_3 or $m_2 = m_3$ (Why?), which contradicts our conclusion (from instability) that w_2 prefers m_1 to m_2 .

Implement each iteration in constant time to get running time $\propto n^2$

Initially, all men and all women are free While there is at least one free man who has not proposed to every woman Choose such a man m m proposes to the highest-ranked woman w on his list to whom he has not yet proposed If w is free. then she becomes engaged to melse if w is engaged to m' and she becomes engaged to mm' becomes free Otherwise, *m* remains free Return set S of engaged pairs

Implement each iteration in constant time to get running time $\propto n^2$

Initially, all men and all women are free While there is at least one free man who has not proposed to every woman Choose such a man m m proposes to the highest-ranked woman w on his list to whom he has not yet proposed If w is free. then she becomes engaged to melse if w is engaged to m' and she becomes engaged to mm' becomes free Otherwise, *m* remains free Return set S of engaged pairs

Implement each iteration in constant time to get running time $\propto n^2$

Initially, all men and all women are free While there is at least one free man who has not proposed to every woman Choose such a man *m* Linked list m proposes to the highest-ranked woman w on his list to whom he has not yet proposed If w is free. then she becomes engaged to melse if w is engaged to m' and she becomes engaged to mm' becomes free Otherwise, *m* remains free Return set S of engaged pairs
